

Platforms used in excersize

- Host machine Microsoft Windows 11 Home
- Service 1 and Storage ubuntu:22.04
- Service 2 mcr.microsoft.com/dotnet/sdk:9.0
- Docker Desktop 4.44.3
- Docker Compose version v2.39.1-desktop.1

Uptime and disk space measure the containers own uptime and the space available inside the container or something. I don't know how usefull these can be as I don't even have that much space in my host what the docker container says it has :D(900gb in container and 200gb on host). These are probably not the things you want to measure inside container.

The advantage of storage method of storage container is that the volumes can be customised in many ways. Such as the driver. You can even use same volume in different docker-composes with external attribute.

Other points straight from documentation:

- Volumes are easier to back up or migrate than bind mounts.
- You can manage volumes using Docker CLI commands or the Docker API.
- Volumes work on both Linux and Windows containers.
- Volumes can be more safely shared among multiple containers.
- New volumes can have their content pre-populated by a container or build.

- When your application requires high-performance I/O.

volume storage can be cleared with command "docker compose down -v"

What was difficult?

The difficult part I think was getting the C# application working properly because I had not previously set it inside container. Other was the setup. I had first made every container to listen on 8199 and then realized I had to use different port for every one of them. The most difficult of all was to realize my docker had something broken and I needed to reinstall it.

Overall I have experience working with docker because of the Tite system administrator role. So this was pretty straight forward and nothing new.
